Boric oxide, the pure form of B$_2$O$_3$, is a hard glassy material, granular in texture. Exposed to the atmosphere it slowly absorbs water, reverting to boric acid. It is soluble in water but at a much slower rate than boric acid. Approximately 56.3 kg of boric oxide are the chemical equivalent of 100 kg of boric acid.

Boric oxide is used where B$_2$O$_3$ is required without the presence of sodium or calcium and/or where water would be detrimental to the process.

**Applications and benefits**

**Specialty glasses**
Pure B$_2$O$_3$ is needed for the production of certain types of glasses including optical and telescope lenses, medical glasses (ampoules), electronic glasses and glass-ceramic composites. The general benefits of using B$_2$O$_3$ in glass formulations are reduction of melting temperature, increased thermal resistance and mechanical strength, and enhanced aqueous and chemical durability.

**Specialty ceramics**
Boric oxide is used to produce various types of high strength and heat-resistant ceramic products such as boron carbide, boron nitride, titanium and zirconium diborides, as well as elemental boron.

**Refractories**
It is used in the manufacture of chemically bonded firebricks and castables which require resistance to high temperature, abrasion and corrosion. Boric oxide is used as a binder for magnesia-based refractory bricks and as a stabilizer for dolomite refractory bricks commonly used in steel smelting furnaces.

**Glazes and enamels**
Boric oxide increases the strength, scratch resistance, and chemical resistance of ceramic wares such as wall and floor tiles, tableware and porcelain, and of enameled appliances. Generally, boric oxide which has a capacity to increase yields is used for a combination of reasons, the final glaze or enamel benefiting from its influence on both the melting and physical properties of the product.

**Chemical reactions**
Boric oxide is used in the preparation of element boron, boron halides, sodium borohydride, metallic borates, and borate esters. It is also used as a catalyst in the conversion and synthesis of many organic compounds.

**Metallurgy**
Boric oxide is an excellent solvent for metallic oxides at high temperatures. In the field of metallurgy, boric oxide is used in the preparation of special welding and soldering fluxes, in chemical-bonded refractories, in the hardening of steel, and in the production of alloys with iron, nickel or manganese. It is also used to produce amorphous metal and rare-earth magnets.
Physical and chemical properties

The normal glassy form of boric oxide has no definite melting point. It begins to soften at about 325°C (617°F). Two crystalline forms can be obtained under high pressure. One of these can also be made at atmospheric pressure. The melting point of the latter has been reported as 450°C ±2°C if made at atmospheric pressure and 465°C ±10°C if made at high pressure.

Stability
Boric oxide is a hygroscopic product. Care should therefore be taken to avoid exposure to water or humidity, as this may cause caking. If wetted it reacts exothermically, forming boric acid. Also, it is, of course, essential to maintain the integrity of the packaging.
